

This graph shows the rate of deaths (per 100,000 population) due to mental disorders in different sex averaged over all countries with respect to age in 2017. Age is divided into different age groups and we see the in an otherwise increasing rate with age, there is an inflection point and local minima during age 65 to 69 in males while the same is absent in females. However, after this age, the rates increase sharply in both sexes and point towards an increased focus on older adults for mental health issues. For more details on considered disorders, see code.
